

Patient 20

Report A

6555191 06/07/2016 MR Head

65551 91 06/07/2016 MR MRA

indication:

Right homonymous hemianopia ATV transient visual loss, upgoing plantar-plantar upgoing. Hameorrhage on CT, AF2CAA

Findings:

Note is made of the (external) CT head study dated 05/07/16. There is T1 shortening, restricted diffusion and susceptibility in the left occipital lobe, corresponding to the acute haematoma demonstrated on the CT study. High T2/FLAIR signal changes in the periventricular, deep and subcortical white matter of the frontoparietal lobes bilaterally are in keeping With moderate Small vessel disease. There are a few foci of Susceptibility in the peripheral subcortical white matter of both cerebral hemispheres consistent with microhaemorrhages.

The intracranial arteries are of normal appearances.

Impression:

Acute left occipital hematoma and a few peripheral microhaemorrhages, possibly from cerebral amyloid angiopathy.
